

Gossans as vectors to critical minerals deposits: An overview of project results for Nunavut

Marie-Claude Williamson

NRCan-Geological Survey of Canada

Methodology

Percival and Williamson (2016)

- Highly weathered Fe-rich soils overlying sulphide-rich bedrock.

- Remote predictive mapping using satellite imagery: detection, extent, morphology, mineralogy.

- Identify gossans with elevated values of base and noble metals.

- Mineralized bedrock

Gossans mapped in Nunavut

GEM GeoNorth
2021-2023

Detecting gossans using satellite imagery

Example: High Lake, NU

A. LANDSAT 7

Natural Colour Composite

1:100,000

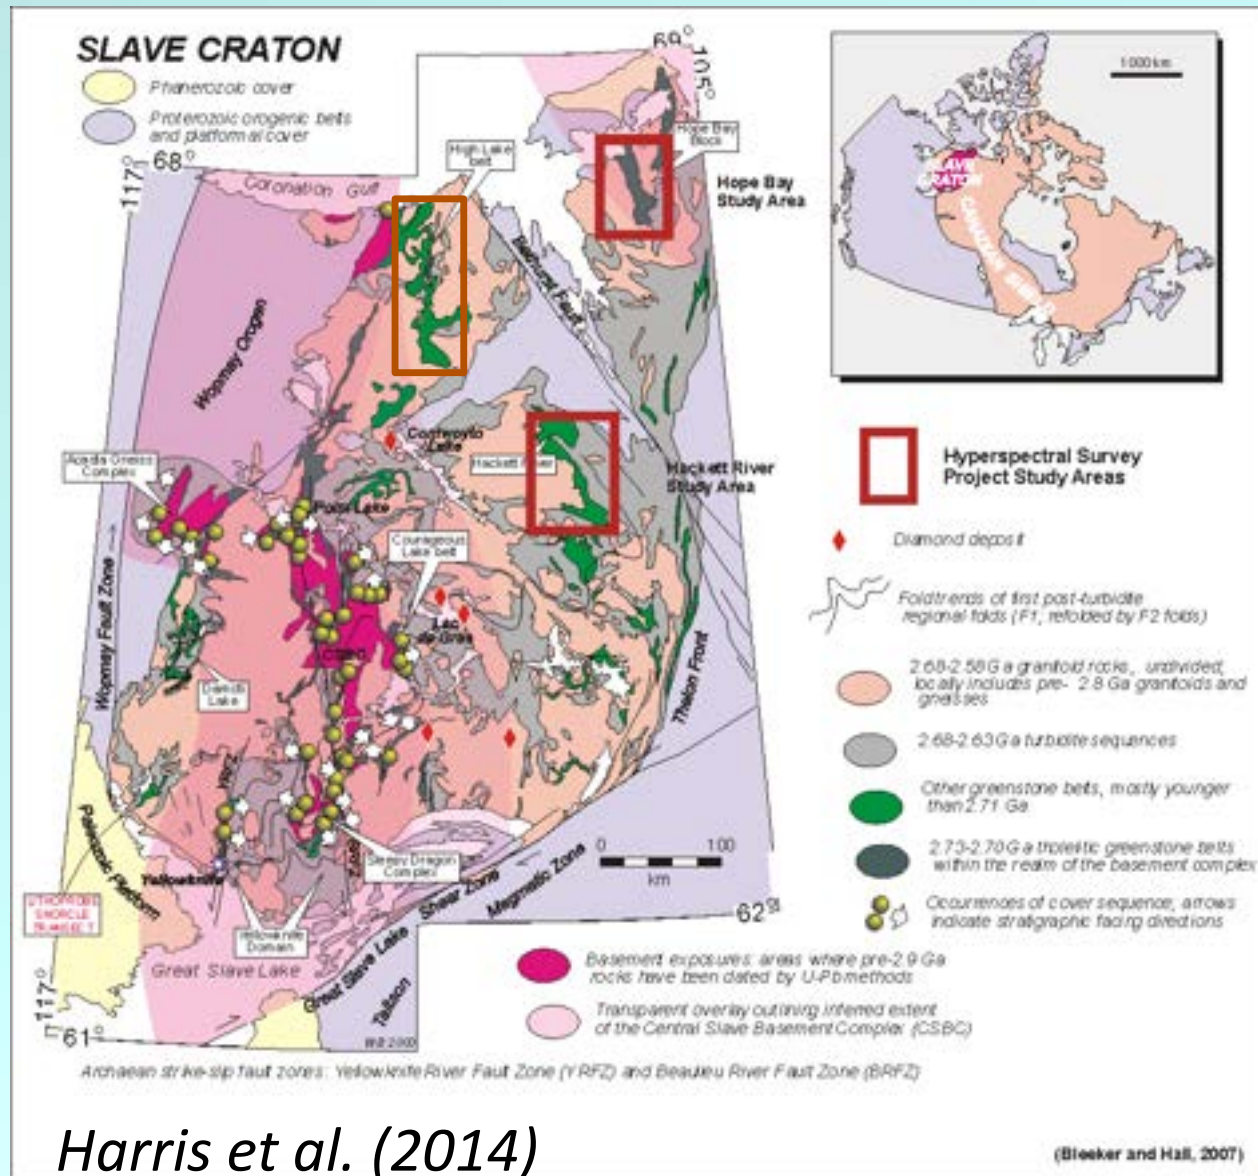

Spatial resolution 30 m

B. HYPERSPECTRAL

Natural Colour Composite

1:10,000

Spatial resolution 1 m

Harris et al. (2014)

Nunavut Mining Symposium 2023

High Lake, NU

C. ESRI World Imagery

Spatial resolution 1.5 m

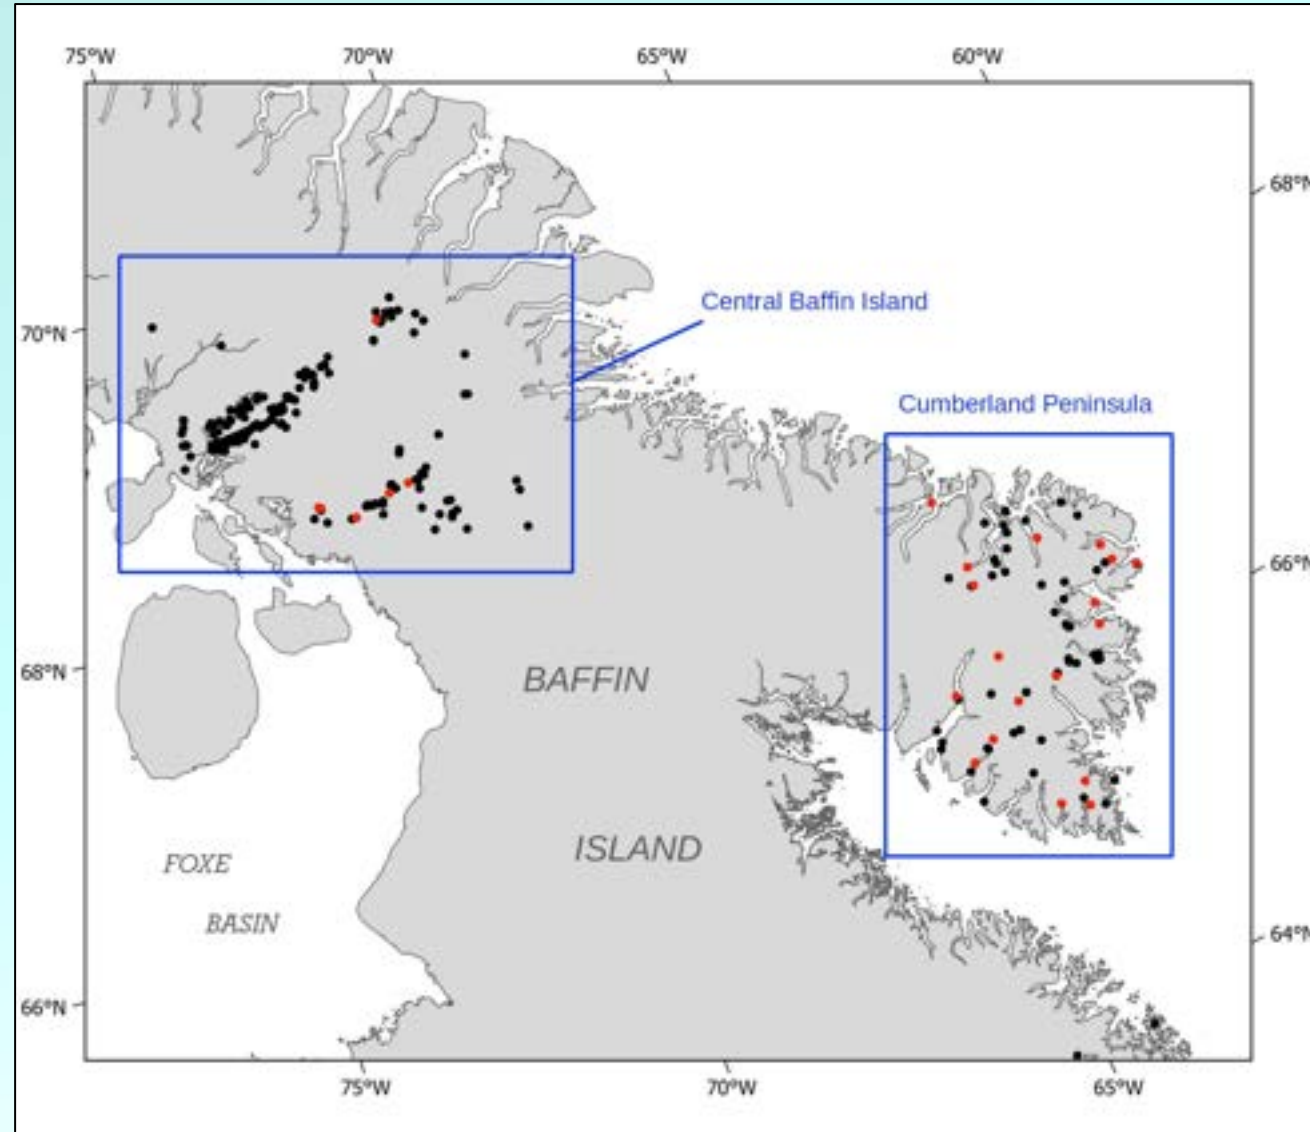

- Detect gossans
- Morphology

D. PRISMA (Hyperspectral)

Spatial resolution 30 m

- Spectral signatures

A closer look at gossans mapped on Baffin Island

Conclusions and Future Work

- Gossans exposed in Nunavut display a wide range of shapes and sizes. Some gossans contain high concentrations of critical minerals, others do not. A systematic approach using satellite imagery and RPM techniques focuses the search for significant mineral concentrations in the host bedrock.
- A collective effort is needed to (1) compare existing databases on mineral showings and gossans in their specific geological context, and (2) search the land for more gossans and mineral showings. The outcomes will be to reduce the uncertainties and costs of mineral exploration and increase the number of potential economic targets.
